## **1 Glossary of Terms**

This glossary provides definitions for OpenCPI-specific and industry-wide terms and acronyms used in OpenCPI documentation.

## 1.1 OpenCPI Terminology

This section provides definitions for terms that are specific to OpenCPI.

### ACI

See [Application Control Interface](#).

### adapter worker

An **adapter worker** is the [worker](#) used when two connected [HDL workers](#) are not connectable in some way due to different interface choices in the [OWD](#). Adapter workers are normally inserted automatically as needed, e.g. between a worker that has a 16-bit bus and one with a 32-bit bus, or HDL workers in different clock domains. These workers are considered part of the OpenCPI [framework](#) and not created by users. See also [worker](#).

### application

[noun] In the context of component-based development, an **application** is a composition or assembly of connected components that, as a whole, perform some useful function. See also [component](#).

[adjective] The term **application** can also be used to distinguish functions or code from infrastructure to support the execution of a component-based application; e.g., an [HDL device worker](#) vs. an [application worker](#).

### Application Control Interface (ACI)

The **Application Control Interface (ACI)** is an [application](#) launch and control API for executing XML-based OpenCPI applications within a C++ or Python program. See the chapter on the ACI in the [OpenCPI Application Development Guide](#) for more information.

### application worker

An **application worker** is the implementation of a [component](#) used in an [application](#), generally portable and hardware independent.

### argument

See [operation argument](#).

### artifact

An **artifact** is a file that contains executable code for one or more [workers](#), built for a specific [platform](#). An artifact is a binary file that results from building some assets. See the overview in the [OpenCPI Application Development Guide](#) for more information.

### asset

An **asset** is an object that is developed for OpenCPI, including [applications](#), [components](#), [workers](#), [protocols](#), [platforms](#), [primitives](#) and other asset types. An asset is developed in a [project](#) and is defined by an [XML](#) file.

### ***authoring model***

An **authoring model** is a method for creating [component](#) implementations in a specific language using a specific API between the [worker](#) and its execution environment. An authoring model represents a particular way to write the source code and [XML](#) for a worker and is usually associated with a class of processors and a set of related languages. Existing models include [RCC](#), [HDL](#) and [OCL](#). See the chapter on authoring models in the [OpenCPI Component Development Guide](#) for more information.

### ***back pressure***

**Back pressure** is the resistance or force opposing the desired flow of data through an [application](#). Back pressure within an OpenCPI system is a common occurrence that happens when [worker](#) output is temporarily not possible due to processing or communication congestion from whatever the output is connected to. Back pressure can be the result of resource-loading issues or passing data between [containers](#).

### ***build configuration***

A **build configuration** is a set of [parameter](#) property (compile-time) values to use when building a [worker](#). See the chapter on worker build configuration XML files in the [OpenCPI Component Development Guide](#) for more information.

### ***CDK***

See [Component Development Kit](#)

### ***component***

A **component** is the interface “contract” specified by an [OpenCPI Component Specification \(OCS\)](#) and implemented by a [worker](#). A component performs a well-defined function regardless of implementation. A component has [ports](#) and [properties](#). See the chapter on component specifications in the [OpenCPI Component Development Guide](#) for more information.

### ***Component Development Kit (CDK)***

The OpenCPI **Component Development Kit (CDK)** is the set of OpenCPI tools, scripts, documents, and libraries used for developing [components](#), [workers](#) and other [assets](#) in [projects](#).

### ***component library***

A **component library** is a collection of [component specifications](#), [workers](#) and [test suites](#) that can be built, exported, and installed to support [applications](#). See the chapter on component libraries in the [OpenCPI Component Development Guide](#) for more information.

### ***component specification***

See [OpenCPI Component Specification \(OCS\)](#).

### **component unit test suite**

A **component unit test suite** is a collection of test cases in a [component library](#) for testing all the [workers](#) in the library that implement the same spec ([OCS](#)) across all available [platforms](#). The workers that are tested can be written to different [authoring models](#) or languages or simply be alternative source code implementations of the same [spec](#). The OpenCPI unit test framework manages multiple dimensions of worker testing, with automation to minimize test design and preparation efforts. See the chapter on worker unit testing in the [OpenCPI Component Development Guide](#) for more information.

### **configuration property**

A **configuration property** is a writeable and/or readable value specified in the [OCS](#) or [OWD](#) that enables [control software](#) to control and monitor a [worker](#). Configuration properties (usually abbreviated to **properties**) are logically the knobs and meters of the worker's "control panel". Each worker may have its own, possibly unique, set of configuration properties which can include hardware resources such registers, memory, and state. Properties can be specified as compile time or runtime. See the chapter on property syntax and ranges in the [OpenCPI Component Development Guide](#) for more information. See also [configuration property accessibility](#).

### **configuration property accessibility**

**Configuration property accessibility** is the set of declarations within an [OCS](#) or [OWD](#) that indicate when it is valid to read from or write to a [configuration property](#). The various accessibility attributes (defined in the [OpenCPI Component Development Guide](#)) establish the rules in relation to the worker's [lifecycle](#) and may declare the property as fixed at build time (see [parameter](#)).

### **container**

A **container** is the OpenCPI infrastructure element that "contains," manages, and executes a set of [workers](#). Logically, the container "surrounds" the workers, mediating all interactions between the workers and the rest of the system. A container typically provides the OpenCPI runtime environment for a particular processor in the system. See the section on the RCC worker interface in the [OpenCPI RCC Development Guide](#) for more information on RCC containers. See the section on HDL container XML files in the [OpenCPI HDL Development Guide](#) for more information on HDL containers.

### **control-application**

A **control-application** is the conventional application (e.g. "main program") that constructs and runs component-based [applications](#). See the chapter on the [ACI](#) in the [OpenCPI Application Development Guide](#) for more information.

## **control interface**

The **control interface** is the interface as seen by [HDL worker](#) code that an HDL [container](#) uses to provide (at a minimum) a control clock and associated reset into the worker, convey life cycle control operations like **initialize**, **start** and **stop**, and access the worker's configuration properties as specified in the [OCS](#) and [OWD](#). See the section on the control interface in the [OpenCPI HDL Development Guide](#) for more information.

## **control operations**

**Control operations** are a fixed set of operations that every [worker](#) may have. These operations implement a common control model that allows all workers to be managed without having to customize the management infrastructure software for each worker, while [configuration properties](#) are used to specialize [components](#). The most commonly used control operations are “start” and “stop”. See the section on lifecycle control operations in the [OpenCPI Component Development Guide](#) for more information.

## **control plane**

In OpenCPI, the **control plane** is the control and configuration infrastructure for runtime [lifecycle](#) control and configuration of [worker](#) instances throughout the system at runtime. See the control plane introduction in the [OpenCPI Component Development Guide](#) for more information.

## **control software**

**Control software** is the software that launches and controls OpenCPI applications, either the standard OpenCPI utility **ocpi-run** or custom C++ or Python programs that perform the same function embedded inside them using the [Application Control Interface](#) application launch and control API. See the control plane introduction in the [OpenCPI Component Development Guide](#) for more information. See also [control-application](#).

Control software generally launches, configures and controls an application and the runtime workers that make up the application. A proxy, meanwhile, is a worker within an application that can control and configure other workers. See the [OpenCPI RCC Development Guide](#) for more information. See also [device proxy worker](#).

## **core project**

The OpenCPI **core project** is a built-in OpenCPI [project](#) ([package ID](#) **ocpi.core**) that contains the minimum set of [workers](#) and infrastructure [VHDL](#) for OpenCPI [framework](#) operation on software and [FPGA](#) simulators.

## **data interface**

A **data interface** is the set of [ports](#) defined in a [worker's OCS](#) that convey data, message boundaries, [opcodes](#) and EOF into and out of the worker and which implement flow control.

### ***data plane***

In OpenCPI, the **data plane** is a data-passing infrastructure that allow [workers](#) of all types to consume/produce data from/to other workers in an [application](#) regardless of the container on which the workers are executing in (or the processor on which they are executing). See the data plane introduction in the [OpenCPI Component Development Guide](#) for more information.

### ***device proxy worker***

A **device proxy worker** is a software [worker](#) (RCC/C++) that is specifically paired with one or more [HDL device workers](#) in order to translate a higher-level control interface for a class of devices into the lower-level actions required on a specific device. See the section on controlling slave workers from proxies in the [OpenCPI RCC Development Guide](#) and the section on device support for FPGA platforms in the [OpenCPI Platform Development Guide](#) for more information.

### ***device worker***

See [HDL device worker](#).

### ***Digital Radio Controller (DRC)***

The **Digital Radio Controller (DRC)** is a utility [component](#) in the OpenCPI built-in [core project](#) that is used when an [application](#) needs to use radio hardware in the system to control it and to stream sample data to and from it. The “digital radio” functionality in a system usually has antennas for transmitting and receiving RF signals and channels which convert the RF signals to and from baseband digital samples that are produced and consumed by the application. See the section on utility components for applications in the [OpenCPI Application Development Guide](#) for more information.

### ***HDL assembly***

An **HDL assembly** is a fixed composition of connected HDL workers that are built into a complete [FPGA bitstream](#) that can be executed on an FPGA to implement some or all of the components of an OpenCPI application. The HDL code is automatically generated from the HDL assembly's [OHAD](#). See the chapter on preparing HDL assemblies for use by applications in the [OpenCPI Application Development Guide](#) and the [OpenCPI HDL Development Guide](#) for more information.

### ***HDL authoring model***

The **HDL authoring model** is the [authoring model](#) used by VHDL-language and less-supported Verilog-language workers that execute on FPGAs. See the [OpenCPI HDL Development Guide](#) for information about using this authoring model. See also [Hardware Description Language \(HDL\)](#).

### ***HDL build hierarchy***

The **HDL build hierarchy** is the structure in which [FPGA bitstreams](#) are created from other [assets](#). See the section about the HDL build hierarchy in the [OpenCPI HDL Development Guide](#) for more information.

### **HDL build process**

The **HDL build process** is the process of building HDL [assets](#) for different target devices and [platforms](#). See the chapter on building HDL assets in the [OpenCPI HDL Development Guide](#) for more information.

### **HDL card**

An **HDL card** is hardware that contains devices and plugs into a slot on an [HDL platform](#). Devices are either directly attached to the pins on an HDL platform or attached to cards that plug into compatible slots on the platform. Devices on a card are considered to be part of the card, which can be plugged into a certain type of slot on any platform, rather than part of the platform itself. See the sections on device support for FPGA platforms and defining cards that contain devices that plug in to platform slots in the [OpenCPI Platform Development Guide](#) for more information.

### **HDL data interface**

An **HDL data interface** is the set of [ports](#) defined in an [HDL worker's OCS](#) that convey data, message boundaries, [opcodes](#) and EOF into and out of the [HDL worker](#) and which implement flow control. Worker data ports can be implemented as stream or message interfaces. Stream interfaces are FIFO-like with extra qualifying bits along with the data indicating message boundaries, byte enables and EOF. Message interfaces are based on addressable message buffers. See the section on HDL worker data interfaces for OCS data ports in the [OpenCPI HDL Development Guide](#) for more information.

### **HDL device emulator worker**

An **HDL device emulator worker** is a special type of [HDL device worker](#) that acts like a device for test purposes. A device emulator worker provides a mirror image of an HDL device worker's external signals so that it can emulate the device in simulation. See the section on testing device workers with emulators in the [OpenCPI Platform Development Guide](#) for more information.

### **HDL device worker**

An **HDL device worker** is a specific type of [HDL worker](#) designed to support a specific external device attached to an [FPGA](#) such as an ADC, flash memory, or I/O device. HDL device workers are typically developed as part of enabling an [HDL platform](#). See the chapter on device support for FPGA platforms in the [OpenCPI Platform Development Guide](#) for more information.

### **HDL interface**

- (1) For [HDL workers](#), an **HDL interface** is the set of input and output port signals that correspond to a high-level OpenCPI port as defined in the [OCS](#) and [OWD](#) for the HDL worker. An HDL worker has a control interface (for the implicit control port), data interfaces (for the explicit data ports defined in the OCS), and service interfaces (for service ports as defined in the HDL worker's OWD).
- (2) For all [worker](#) types, an **HDL interface** is the implicit control port.

### **HDL platform**

An **HDL platform** is an OpenCPI [platform](#) based on an [FPGA](#) that is enabled to host OpenCPI [HDL workers](#). An HDL simulator is also considered to be an HDL platform. See the chapter on enabling FPGA platforms in the [OpenCPI Platform Development Guide](#) for more information.

### **HDL platform configuration**

An **HDL platform configuration** is a pre-built (usually pre-synthesized) assembly of [HDL device workers](#) that represents a particular reusable configuration of device support modules for a given [HDL platform](#). The HDL code is automatically generated from a brief description in [XML](#). See the section on enabling execution for FPGA platforms in the [OpenCPI Platform Development Guide](#) for more information.

### **HDL platform worker**

An **HDL platform worker** is a specific type of [HDL worker](#) that enables an [HDL platform](#) for use with OpenCPI and provides the infrastructure for implementing control/data interfaces to devices and interconnects external to an [FPGA](#) or simulator, such as [PCIe](#) or clocks. See the section on enabling execution for FPGA platforms in the [OpenCPI Platform Development Guide](#) for more information.

### **HDL primitive**

An **HDL primitive** is an HDL [asset](#) that is lower level than a [worker](#) and can be used (and reused) as a building block for [HDL workers](#). An HDL primitive is either a [library](#) or a [core](#). See the chapter on HDL primitives in the [OpenCPI HDL Development Guide](#) for more information.

### **HDL primitive core**

An **HDL primitive core** is a low-level module that can be built and/or synthesized from source code, or imported as pre-synthesized and possibly encrypted from third parties, or generated by tools like [Xilinx CoreGen](#) or [Intel/Altera MegaWizard](#). An [HDL worker](#) declares which primitive cores it requires (and instantiates). See the chapter on HDL primitives in the [OpenCPI HDL Development Guide](#) for more information.

### **HDL primitive library**

An **HDL primitive library** is a collection of low-level modules compiled from source code that can be referenced in [HDL worker](#) code. An HDL worker declares the HDL primitive libraries from which it draws modules. See the chapter on HDL primitives in the [OpenCPI HDL Development Guide](#) for more information.

### **HDL slot**

An **HDL slot** is an integral part of an [HDL platform](#) that enables an [HDL card](#) to be plugged in so that its attached devices are accessible to the platform. An HDL platform has defined slot types; HDL cards that are designed for the same slot type can be plugged in to the defined slots on the platform. See the sections on device support for FPGA platforms and defining cards that contain devices that plug in to platform slots in the [OpenCPI Platform Development Guide](#) for more information.

### **HDL subdevice worker**

An OpenCPI **HDL subdevice worker** is a special type of [HDL application worker](#) that supports an [HDL device worker](#) defined in another library. See the section on subdevice workers in the [OpenCPI Platform Development Guide](#) for more information.

### **HDL worker**

An **HDL worker** is an HDL implementation of a [component specification](#) with the source code (for example, [VHDL](#)) written according to the HDL authoring model. An HDL worker is usually a hardware-independent, portable [application worker](#) but can alternatively be an [HDL device worker](#) that controls a specific piece of hardware attached to an [FPGA](#). See the chapter on the HDL worker in the [OpenCPI HDL Development Guide](#) for more information.

### **lifecycle state model**

The OpenCPI **lifecycle state model** specifies the control states each [worker](#) may be in and the [control operations](#) which generally change the state a worker is in, effecting a state transition. See the section on the lifecycle state model in the [OpenCPI Component Development Guide](#) for more information.

### **OAS**

See [OpenCPI Application Specification](#).

### **OCS**

See [OpenCPI Component Specification](#).

### **OHAD**

See [OpenCPI HDL Assembly Description](#).

### **OHPD**

See [OpenCPI HDL Platform Description](#).

### **opcode**

See [operation code](#).

### **OpenCL (OCL) authoring model**

The **OpenCL (OCL) authoring model** is the [authoring model](#) used by [Open Computing Language](#) (OpenCL) (C subset/superset)-language workers usually executing on graphics processors. See the **OpenCPI OCL Development Guide** for more information. This OpenCPI authoring model is currently experimental.

### **OpenCPI Application Specification (OAS)**

An **OpenCPI Application Specification (OAS)** is an [XML](#) document that describes the collection of components along with their interconnections and [configuration properties](#) that defines an OpenCPI [application](#). See the chapter on OpenCPI application specification XML documents in the [OpenCPI Application Development Guide](#) for more information.

### **OpenCPI Component Specification (OCS)**

An **OpenCPI Component Specification (OCS)** is an [XML](#) file that describes both [configuration properties](#) and zero or more data [ports](#) (referring to [protocol specifications](#)) of a [component](#), establishing interface requirements for multiple implementations ([workers](#)) in any [authoring model](#). Also referred to as a *component spec* or *spec file*. See the chapter on component specifications in the [OpenCPI Component Development Guide](#) for more information.

### **OpenCPI HDL Assembly Description (OHAD)**

An **OpenCPI HDL Assembly Description (OHAD)** is an [XML](#) file that describes an [HDL assembly](#). See the chapter on HDL assemblies for creating and executing FPGA bitstreams in the [OpenCPI HDL Development Guide](#) for more information.

### **OpenCPI HDL Platform Description (OHPD)**

An **OpenCPI HDL Platform Description (OHPD)** is an [XML](#) file that describes an [HDL platform](#). An OHPD contains the same information as the [OWD](#) for the [HDL platform worker](#) and also describes the devices (controlled by [HDL device workers](#)) that are attached to the HDL platform and available for use. See the section on enabling execution for FPGA platforms in the [OpenCPI Platform Development Guide](#) for more information.

### **OpenCPI Protocol Specification (OPS)**

An **OpenCPI Protocol Specification (OPS)** is an [XML](#) file that describes the allowable data messages ([operation codes](#)) and payloads ([operation arguments](#)) that may flow between the ports of [components](#). See the chapter on protocol specifications in the [OpenCPI Component Development Guide](#) for more information.

### **OpenCPI System support Project (OSP)**

An **OpenCPI System support Project (OSP)** is an OpenCPI [project](#) that contains OpenCPI [assets](#) whose purpose is to enable and test a particular system (of [platforms](#)) to be used by OpenCPI. OSPs fulfill what is generally meant by the more generic industry term: Board Support Package. An OSP may contain assets to support multiple related systems. See also [Board Support Package \(BSP\)](#).

## **OpenCPI Worker Description (OWD)**

An **OpenCPI Worker Description (OWD)** is an [XML](#) file that describes the [worker](#) and references the [component specification](#) it is implementing. See the chapter on worker descriptions in OWD files in the [OpenCPI Component Development Guide](#) for more information.

## **operation argument**

An **operation argument** is one of the data values in the payload data defined for a particular operation (message type) within a [protocol specification](#) whose type information is determined by the protocol [XML](#).

## **operation (within a protocol)**

An **operation** is a message type encapsulating zero or more [operation arguments](#) within an [OpenCPI protocol specification](#).

## **operation code (opcode)**

An **operation code (opcode)** is an ordinal that indicates which of the possible [operations](#) in a protocol is present.

## **OPS**

See [OpenCPI Protocol Specification](#).

## **OSP**

See [OpenCPI System support Project](#).

## **OWD**

See [OpenCPI Worker Description](#).

## **package ID**

A **package ID** is the globally-unique identifier of an OpenCPI [asset](#). A [project's](#) package ID is used when it is depended on by other projects. A [component's](#) package ID is used to reference it in [applications](#) or [workers](#). While all assets have package IDs (either explicitly specified or inferred from the directory structure), only certain assets are currently identified by their package IDs. See the section on package IDs in the [OpenCPI Component Development Guide](#) for more information.

## **parameter**

A **parameter** is an immutable [configuration property](#) that is set at build time, allowing software compilers and hardware compilers to optimize accordingly. See the sections on properties that are build-time parameters, property accessibility attributes, and the parameter attribute of property elements and [SpecProperty](#) elements in the [OpenCPI Component Development Guide](#) for more information.

### ***platform***

An OpenCPI **platform** is a particular type of processing hardware and/or software that can host a [container](#) for executing OpenCPI [workers](#) based on [artifacts](#). Platforms may be based on [CPUs](#), [GPUs](#) or [FPGAs](#). See the chapter on OpenCPI systems and platforms in the [OpenCPI Platform Development Guide](#) for more information.

### ***platform worker***

See [HDL platform worker](#).

### ***port***

An OpenCPI **port** is an interface of a [component](#) that allows it to communicate with other components using a [protocol](#). Ports are unidirectional: input or output, consumer or producer. In OpenCPI, a [port](#) is a high-level data flow interface in and out of all types of workers. In the [VHDL](#) and [Verilog](#) languages, however, a “port” refers to the individual signals (of any type) that are the inputs and outputs of an entity (VHDL) or module (Verilog). See the chapter on component specifications in the [OpenCPI Component Development Guide](#) for more information.

### ***port readiness***

**Port readiness** indicates whether an input [port](#) has data to be consumed or an output port has capacity to produce data (e.g. no [back pressure](#)). Input ports are ready when there is message data present that has not yet been consumed by the [worker](#). Output ports are ready when buffers are available into which they may place new data.

### ***project***

An OpenCPI **project** is a work area (and directory) in which to develop OpenCPI [components](#), [libraries](#), [applications](#), and other [platform](#)- and device-oriented [assets](#). See the chapter on developing OpenCPI assets in projects in the [OpenCPI Component Development Guide](#) for more information.

### ***project registry***

An OpenCPI **project registry** is a directory that contains references to [projects](#) in a development environment so they can refer to (and depend on) each other. Development activity takes place in the context of a project registry that specifies available projects to use. See the section on the project registry in the [OpenCPI Component Development Guide](#) for more information.

### ***property***

See [configuration property](#).

### ***protocol specification***

See [OpenCPI Protocol Specification \(OPS\)](#).

## **protocol summary**

A **protocol summary** is the set of summary attributes, whether inferred from the messages specified for the [protocol](#), or specified directly as attributes of the protocol, and indicates the basic behavior of a port using a protocol. A protocol summary can also be present when messages are specified, and can override the attributes inferred from the message specifications. See also [Component Development Kit \(CDK\)](#).

## **RCC, RCC authoring model**

See [Resource-Constrained C \(RCC\) authoring model](#).

## **Resource-Constrained C (RCC) authoring model**

The **Resource-Constrained C (RCC) authoring model** is the [authoring model](#) used by C or C++ language workers that execute on [General-Purpose Processors](#) (GPPs). The “Resource Constrained” prefix indicates that the environment may be constrained to use a limited set of library calls; see the [OpenCPI RCC Development Guide](#) for more information.

## **registry**

See [project registry](#).

## **RCC worker**

An **RCC worker** is an [RCC](#) implementation of an OpenCPI [component specification](#) with the source code (for example, C++ or Python) written according to the [RCC authoring model](#). An RCC worker can act as a [device proxy worker](#). See the [OpenCPI RCC Development Guide](#) for more information.

## **run condition**

A **run condition** is the specification by an [RCC worker](#) as to when it should execute, based on a combination of [port readiness](#) and/or some amount of time having passed. The commonly-used default run condition is when all ports are ready, with no consideration of time passing.

## **run method**

A **run method** is a non-blocking software method that is executed when a [worker's run condition](#) is satisfied, as determined by its [container](#).

## **spec file**

**Spec file** (and *component spec*) is shorthand notation for an [OpenCPI Component Specification](#) file.

## **SpecProperty**

A **SpecProperty** is an [XML](#) element that adds a [worker](#)-specific attribute to a [configuration property](#) already defined in the [component spec](#). See the section on worker descriptions in OWD XML files in the [OpenCPI Component Development Guide](#) for more information.

## **system**

In OpenCPI, a **system** is a collection of [platforms](#) usually in a box or on a system bus or fabric.

## **target**

An OpenCPI **target** is the entity for which an [asset](#) should be built (compiled, synthesized, place-and-routed, etc.) In OpenCPI, build targets are usually [platforms](#) (particular products or particular operating system releases and architectures). When a set of platforms shares a common processor architecture family, it is *sometimes* possible to build for the "family" and the results of that build can be used for all the platforms. See the section on RCC compilation and linking options in the [OpenCPI RCC Development Guide](#) and the section on HDL build targets in the [OpenCPI HDL Development Guide](#) for more information.

## **worker**

An OpenCPI **worker** is a specific implementation (and possibly a runtime instance) of a [component specification](#) with the source code written according to an [authoring model](#). See the introductory chapter on workers in the [OpenCPI Component Development Guide](#) for more information.

## **worker property**

A **worker property** is a [configuration property](#) related to a particular implementation (design) of a [worker](#); that is, one that is not necessarily common across a set of implementations of the same high-level [component specification](#) (OCS). A worker property is additional to the properties defined by the component specification being implemented. See the section on how a worker access its properties in the [OpenCPI RCC Development Guide](#) and the sections on property access and property data types in the [OpenCPI HDL Development Guide](#) for more information.

## **unit test**

See [component unit test suite](#).

## **Zero-Length Message (ZLM)**

A **Zero-Length Message (ZLM)** is a data payload with no [operation arguments](#) present when a [protocol specification](#) specifies such an [operation code](#) with no data fields.

## 1.2 Industry Terminology

This section provides definitions for industry-wide terms relating to OpenCPI.

### **Advanced eXtensible Interface (AXI)**

**Advanced eXtensible Interface (AXI)** is an industry-standard bus used by ARM processors.

### **Advanced RISC Machine (ARM)**

**Advanced RISC Machine (ARM)** is a widely-used processor architecture originally based on a 32-bit reduced instruction set (RISC) computer.

### **ARM**

See [Advanced RISC Machine](#).

### **AXI**

See [Advanced eXtensible Interface](#).

### **Board Support Package (BSP)**

A **Board Support Package (BSP)** is the layer of software in an embedded system that contains hardware-specific drivers and other routines that allow a particular operating system (usually a real-time operating system) to function in a particular hardware environment integrated with the operating system itself. An [OpenCPI System support Project \(OSP\)](#) performs the function of a BSP in OpenCPI.

### **Central Processing Unit (CPU)**

A **Central Processing Unit (CPU)** is the electronic circuitry that executes instructions comprising a computer program. A CPU performs basic arithmetic, logic, controlling, and input/output (I/O) operations specified by the instructions in the program, in contrast with external components such as main memory and I/O circuitry and specialized processors such as [Graphics Processing Units](#) (GPUs).

### **CPU**

See [Central Processing Unit](#).

### **Digital Signal Processor (DSP)**

A **Digital Signal Processor (DSP)** is a specialized microprocessor chip with an architecture that is optimized for the operational needs of [digital signal processing](#).

### **digital signal processing**

**Digital signal processing** (also abbreviated to “DSP”) is the use of digital processing by [General-Purpose Processors \(GPPs\)](#) or [Digital Signal Processors \(DSPs\)](#) to perform a wide variety of signal processing operations. The digital signals processed in this way are a sequence of numbers that represent samples of a continuous variable in a domain such as time, space, or frequency.

## **DSP**

See [Digital Signal Processor](#). This acronym is sometimes also used more generically for [digital signal processing](#) as a class of computational algorithms.

## **eXtensible Markup Language (XML)**

**eXtensible Markup Language (XML)** is a standardized markup language that defines a set of rules for encoding documents in a format which is both human- and machine-readable.

## **Field-Programmable Gate Array (FPGA)**

A **Field-Programmable Gate Array (FPGA)** is an integrated circuit that is designed to be configured by a customer or a designer after manufacturing. The FPGA configuration is generally specified using a [hardware description language](#) (HDL), similar to that used for an Application-specific Integrated Circuit (ASIC).

## **FPGA**

See [Field-Programmable Gate Array](#).

## **FPGA bitstream**

In the context of FPGA development, an **FPGA bitstream** is a single, standalone artifact, resulting from building an HDL assembly, that is ready for loading onto an actual, physical FPGA.

## **framework**

A **framework** is a development and runtime tool set for a particular class of software, firmware, or [gateway](#) development. OpenCPI is a framework.

## **gateway**

**Gateway** is source code written in an [HDL](#) for an [FPGA](#). Gateway is like software because it is fully programmable, but it compiles to fully parallel logic, which allows it to compute efficiently like hardware. Gateway solutions achieve performance and flexibility by running on FPGAs.

## **General-Purpose Processor (GPP)**

A **General-Purpose Processor (GPP)** is a processor designed for general-purpose computers such as PCs or workstations and for which computation speed is the primary concern. See also [Central Processing Unit \(CPU\)](#).

## **GPP**

See [General-Purpose Processor](#).

## **GPU**

See [Graphics Processing Unit](#).

## **Graphics Processing Unit (GPU)**

A **Graphics Processing Unit (GPU)** is a chip or electronic circuit capable of rendering graphics for display on an electronic device. In the last decade, GPUs have also been used for more general-purpose computing when algorithms can exploit the same highly parallel architectures.

## **Hardware Description Language (HDL)**

**Hardware Description Language (HDL)** is a specialized language used to program the structure design and operation of digital logic circuits. In OpenCPI, it is an [authoring model](#) using the [VHDL](#) language and is targeted at [FPGAs](#). [HDL workers](#) should be developed according to the HDL authoring model described in the [OpenCPI HDL Development Guide](#).

### **HDL**

See [Hardware Description Language](#).

## **Integrated Synthesis Environment (ISE®) Design Suite**

The Xilinx [Integrated Synthesis Environment \(ISE\) Design Suite](#) is a discontinued software tool for synthesis and analysis of HDL designs, which primarily targets development of embedded firmware for Xilinx [FPGA](#) and Complex Programmable Logic Device (CPLD) integrated circuit (IC) product families. Use of the last released edition continues for in-system programming of legacy hardware designs containing older FPGAs and CPLDs otherwise orphaned by the replacement design tool, [Vivado® Design Suite](#).

## **ISE® Simulator (Isim)**

The **ISE Simulator (ISim)** is the [HDL](#) simulator provided with the Xilinx [ISE® Design Suite](#). In OpenCPI, this simulator is called the **isim** [HDL platform](#).

### **isim**

See [Integrated Synthesis Environment \(ISE®\) Simulator \(ISim\)](#).

## **OCL, OpenCL**

See [Open Computing Language](#).

## **Open Computing Language (OCL, OpenCL)**

The **Open Computing Language (OCL, OpenCL)** is a language and runtime for writing programs that, subject to the availability of appropriate tools, may execute on different types of processors, e.g. [Central Processing Units](#) (CPUs), [Graphics Processing Units](#) (GPUs), [Digital Signal Processors](#) (DSPs), [Field-Programmable Gate Arrays](#) (FPGAs) and other processors or hardware accelerators. OpenCL is an open standard maintained by the non-profit technology consortium [Khronos Group](#).

## **OSS**

See [Open Source Software](#).

## **Open Source Software (OSS)**

**Open Source Software (OSS)** is a type of computer software in which source code is released under a license in which the copyright holder grants users the rights to use, study, change, and distribute the software to anyone and for any purpose. Open Source Software may be developed in a collaborative public manner.

## **PCI**

See [Peripheral Component Interconnect](#).

## **PCIe**

See [Peripheral Component Interconnect Express](#).

### **Peripheral Component Interconnect (PCI)**

**Peripheral Component Interconnect (PCI)** is a local computer bus for attaching hardware devices in a computer and is part of the PCI Local Bus standard. The PCI bus supports the functions found on a processor bus but in a standardized format that is independent of any given processor's native bus. Devices connected to the PCI bus appear to a bus master to be connected directly to its own bus and are assigned addresses in the processor's address space. PCI is a parallel bus, synchronous to a single bus clock. Attached devices can take either the form of an integrated circuit fitted onto the motherboard (called a planar device in the PCI specification) or an expansion card that fits into a slot.

### **Peripheral Component Interconnect Express (PCIe)**

**Peripheral Component Interconnect Express (PCIe)** is a high-speed serial computer expansion bus standard that is designed to replace the older PCI, PCI-X and AGP bus standards. Improvements over the older standards include higher maximum system bus throughput, lower I/O pin count and smaller physical footprint, better performance scaling for bus devices, a more detailed error detection and reporting mechanism and native hot-swap functionality. More recent revisions of the PCIe standard provide hardware support for I/O virtualization.

## **RPM**

See [RPM Package Manager](#).

### **RPM Package Manager (RPM)**

The **RPM Package Manager (RPM)** is a free and open-source package management system used in some Linux distributions. The name "RPM" refers to .rpm file format and to the Package Manager program command itself.

### **System on a Chip (SoC)**

A **system on a chip (SoC)** is a single integrated circuit (IC, or "chip") that integrates all or most components of a computer or other electronic system. SoC is a complete electronic substrate system that may contain analog, digital, mixed-signal or radio frequency functions. Its components usually include a [Graphics Processing Unit](#) (GPU), a [Central Processing Unit](#) (CPU) that may be multi-core, and system memory (RAM). SoCs are in contrast to the common traditional motherboard-based PC architecture, which separates components based on function and connects them through a central interfacing circuit board. SoCs used with OpenCPI typically also contain [FPGAs](#).

## **Verilog**

**Verilog** is a [hardware description language](#) (HDL) used to model electronic systems. Verilog is standardized as IEEE 1364.

### ***VHSIC Hardware Description Language (VHDL)***

**VHDL** is a [hardware description language](#) used in electronic design automation to describe digital and mixed-signal systems such as [FPGAs](#) and integrated circuits (ICs). VHDL can also be used as a general-purpose parallel programming language.

### ***Vivado® Design Suite (Vivado, Xilinx Vivado)***

The [Xilinx Vivado Design Suite](#) is a software suite for synthesis and analysis of [HDL](#) designs. Vivado is an integrated design environment (IDE) with system-to-IC level tools built on a shared scalable data model and a common debug environment. Vivado supersedes Xilinx ISE with additional features for [system on a chip](#) development and high-level synthesis. Vivado WebPACK Edition is a free version of Vivado that provides designers with a limited version of the Vivado Design Suite environment.

### ***Vivado® Simulator***

**Vivado Simulator** is an HDL event-driven simulator that Xilinx provides with [Vivado Design Suite](#) and WebPACK Edition. In OpenCPI, this simulator is called the **xsim** [HDL platform](#).

### ***XML***

See [eXtensible Markup Language](#).

### ***Xsim***

See [Vivado® Simulator](#).
